1 Week 2

For this week, I want to start with some basic definitions covered by professor May in his office, about the definition of spectra / prespectra / generalized cohomology theory. I'll probably skip some of the details in the intro to make sure I can keep on track.

1.1 Intro

1.1.1 Brown Representability Theorem, and Generalized Cohomology

Let $h\mathcal{C}$ denotes the homotopy category of based spaces (that admits a CW structure, as on them weak equivalences and homotopy equivalence are the same), then a functor $F : h\mathcal{C}^{\text{op}} \rightarrow \mathbf{Ab}$ is *representable*, if there exists a based space $Y \in h\mathcal{C}$, such that $F \cong [-, Y]$.

Example 1.1. The *reduced cohomology functor* $\tilde{H}^n(-; A)$ is one, for all $n \geq 0$ and a fixed abelian group A (as coefficient). Let $K(A, n)$ be the *Eilenberg-MacLane Space* of abelian group A and index $n \geq 0$ (i.e. the n th homotopy group $\pi_n(K(A, n)) = A$), then the following group isomorphism holds:

$$\tilde{H}^n(X; A) \cong [X, K(A, n)]$$

Using more adjunction property, since $\pi_n(A, n) = A = \pi_{n+1}(K(A, n+1)) = [S^{n+1}, K(A, n+1)] = [S^n \wedge S^1, K(A, n+1)] \cong [S^n, \Omega K(A, n+1)] = \pi_n(\Omega K(A, n+1))$, there is a homotopy equivalence $K(A, n) \xrightarrow{\sim} \Omega K(A, n+1)$.

(Yeah, need to understand more about the details)

So, the regular cohomology we see on spaces, are one type of representable functors.

The classification of all such functors is given by *Brown Representability Theorem*:

Theorem 1.2. Suppose the functor $F : h\mathcal{C}^{\text{op}} \rightarrow \mathbf{Set}$ satisfies:

- $F(\bigvee_{\alpha} X_{\alpha}) \cong \prod_{\alpha} F(X_{\alpha})$ (i.e. maps coproduct to product).

- F maps homotopy pushouts (I believe this is the reduced mapping cylinder?) to weak pullbacks (omit the uniqueness of maps). This condition is equivalent to Mayer-Vietoris axiom (which seems like a weaker form of the gluing axiom in sheaf theory, and restrict to CW subcomplexes instead of open sets).

Then, F is representable by some CW complex C , or $F \cong [-, C]$.

The converse for the theorem also holds, as $[-, C]$ also satisfies the above axioms (need more details here).

Here is a definition of generalized cohomology:

Definition 1.3. A *generalized cohomology*, is a sequence of spaces $\{E_n\}_{n \geq 0}$, with homotopy equivalences $\{\epsilon_n : E_n \xrightarrow{\cong} \Omega E_{n+1}\}_{n \geq 0}$.

In a more explicit form, $E^n(X) := [X, E_n]$ has all $n \geq 0$ satisfies $E^n(X) = [X, E_n] \cong [X, \Omega E_{n+1}]$, which is naturally a group (and an abelian group for $n \geq 2$, due to the abelian group structure on $[X, \Omega^m Y]$ for $m \geq 2$).

I remembered the motivation is that, by Brown Representability Theorem, if a sequence of representable functors $E^* : h\mathcal{C}^{\text{op}} \rightarrow \mathbf{Set}$ satisfy similar properties to ordinary cohomology (for instance, the connecting morphism $E^n \rightarrow E^{n+1}$, and excision axiom?), then Brown Representability Theorem guarantees it must be the above form. So, they're precisely all the generalized cohomology.

1.1.2 Ω -Prespectra, Prespectra, and Spectra

When talking about generalized cohomology, we have a sequence of spaces $\{E_n\}_{n \geq 0}$, together with homotopy equivalences $\epsilon_n : E_n \xrightarrow{\cong} \Omega E_{n+1}$, which is a prototype of what's called *Ω -Prespectra*.

In general, fixing a based space $X \in h\mathcal{C}$, the sequence $\{\Sigma^n X\}_{n \geq 0}$ has a collection of natural maps $\{\text{id}_n : \Sigma(\Sigma^n X) \rightarrow \Sigma^{n+1} X\}_{n \geq 0}$, which the adjunction (Σ, Ω) guarantees a collection of maps $\{\eta_n : \Sigma^n X \rightarrow \Omega(\Sigma^{n+1} X)\}_{n \geq 0}$. In general these maps are not homotopy equivalence, so these type of sequences are a type of *Prespectra*.

For the strongest form possible, if such map $\epsilon_n : E_n \rightarrow \Omega E_{n+1}$ is a homeomorphism, then these are called *Spectra*.
